UNDERSTANDING Sepsis in Newborns

What is sepsis?

Sepsis is a term used to describe an infection in the blood that may spread to other parts of the body. In newborns, there are two common types of sepsis.

**Early onset sepsis**

Occurs within 7 days of birth. Risk factors include:

- Premature birth or low birth weight
- Mother’s water broke more than 18 hours before birth (premature rupture of the membranes)
- Infection in the mother or in the placenta (chorioamnionitis)

**Late onset sepsis**

Develops when the baby is at least 7 days old, and is usually due to exposure to germs after birth.

Risk factors include:

- Premature birth or low birth weight
- Baby treated for other health problems in the hospital

What are the symptoms of sepsis?

Symptoms of sepsis in newborns can include:

- Low activity level
- Limited interest in eating or poor feeding from breast or bottle
- Abnormal body temperature (can be too low or too high)
- Pale skin color
- Vomiting
- Diarrhea
- Bloating
- Yellow color of the skin and the whites of the eyes (jaundice)
- Trouble breathing, or a brief stop in breathing (apnea)
- Decreased heart rate (bradycardia)
- Tremors or seizures
Treating Sepsis

Does sepsis cause long-term problems?
When treated, most newborns recover from sepsis. However, some babies develop complications such as meningitis (infection of the tissue around the brain and spinal cord) or pneumonia. These complications may result in longer hospital stays and a higher risk for long-term problems. The NICU team will watch your baby for signs of these problems. Early treatment of sepsis can help prevent these other infections.

What treatment will my baby receive?
Newborns with sepsis are treated with antibiotics. Sicker babies may also receive:

- Intravenous (IV) fluids
- Extra oxygen – usually given through a nose tube or a mask
- Mechanical ventilation – a machine that helps your baby breathe using a tube

How will I know how my baby is doing?
Your health care team will keep you up to date on your baby’s progress. They will watch the baby’s vital signs (such as heart rate, breathing, and temperature). They may also take blood samples to see if the infection is improving.

What will happen next?
Many babies respond well to treatment for sepsis; however, each baby is different. Talk to your baby’s health care team. They can answer any questions you have about your baby.

Glossary

Antibiotics – medicines that fight infections caused by bacteria

Apnea – brief stop in breathing

Bradycardia – decreased heart rate

Chorioamnionitis [kor-e-o-am-nee-o-ni-tis] – infection of the placenta and the fluid surrounding the baby

Culture – a sample of blood, urine, or other body fluid that is collected and tested for infection

Jaundice – yellow color of the skin and the whites of the eyes

Meningitis [men-in-jahy-tis] – infection of the tissue around the brain and spinal cord

Pneumonia [noo-mohn-yuh] – infection of the lungs

Ventilator – a machine that helps your baby breathe by pushing air in and out of the lungs

Ask the health care team when you have questions—they are there to help.
